

1) Compare bulk construction versus repeated insertion into an empty tree.

Well, something isn't right. Bulk construction logically should be more efficient than worst case sequential addition. However, that is not what I'm seeing. I expect there is an issue with the testing (I don't know what 'worst' case means, but I'm trying lines in a row), or my implementation.

2) Compare collision detection using the assignment's algorithm with one suggested in the analysis.

In this case, going through all nodes takes significantly longer than the algorithm implemented in the assignment, which takes advantage of a binary tree search. This difference in performance is expected.
